SECURITY CLASSIFICATION OF THIS PAGE(When Data Entered)

✓ diesel fuel. + 2 -

The performance test indicated no change in power and a 3+1-percent increase in fuel consumption. The endurance test indicated no change to slightly less wear, less deposits, no change in the oil consumption rate, and nothing unusual or excessive in the used oil analyses. Analysis of the JP-5 indicated a cetane number within diesel fuel specifications.

Although further tests are necessary to define the effect of random variables on the test results, from this test it can be concluded that the use of JP-5 in the CUE 1790 resulted in no appreciable loss in performance or service life. As a result, JP-5 is considered to be a satisfactory alternative fuel for use in the AVDS 1790-2C diesel engine. ↑

FOREWORD

This work was conducted at the U.S. Army Fuels and Lubricants Research Laboratory (USAFRLRL) located at Southwest Research Institute, San Antonio, Texas under contract DAAK70-79-C-0069 during the period June 1979 through November 1979. The work was funded by the U.S. Army Mobility Equipment Research and Development Command (MERADCOM), Ft. Belvoir, Virginia, with Mr. F.W. Schaekel (DRDME-GL) serving as contract monitor. Project technical monitor was Mr. M.E. LePera, MERADCOM-DRDME-GL.

The author acknowledges the contributions of Messrs. F.C. Owens for assistance in test planning, L. Sievers for assistance in conducting the tests, and E. Lyons for assistance in engine ratings.

I. INTRODUCTION

In order to reduce logistics requirements and assure increased availability of fuels for Army ground-based equipment, MIL-T-5624L, Grade JP-5 turbine fuel^{(1)*} has been identified as an alternate fuel in place of the primary VV-F-800B DF-2 diesel fuel.⁽²⁾

According to Army Regulation AR 703-1, "Coal and Petroleum Products Supply and Management Activities, 15 September 1978," an alternate fuel is "a fuel that provides performance equal to the primary fuel, but may be a restricted item of supply in tactical areas or has environmental limitations. No degradation of performance or service life occurs as a result of the use of an alternate fuel within the prescribed operational range."

MIL-T-5624L, Grade JP-5 is currently specified as an alternate fuel in AR 703-1 for diesel-powered equipment. The decision to include JP-5 as an alternate for DF-2 occurred as a result of two factors. The U.S. Navy at Port Hueneme had conducted considerable work during the 1960's using JP-5 in large bore and medium-speed diesel engines.⁽³⁾ Secondly, the U.S. Army conducted a survey of major diesel engine manufacturers and fuel system suppliers in 1972 to assess the potential problems arising from substitution of JP-5 for DF-2.⁽⁴⁾ The cumulative results of these two factors ultimately led to the decision that JP-5 was an acceptable substitute for DF-2. However, no formal program was established to develop long-term endurance testing which would have provided reliability-maintainability-durability (RAM) data. Only a limited amount of performance testing was done.⁽⁵⁾

More recently, the U.S. Marine Corps (USMC) were considering adopting JP-5 as an alternate fuel for DF-2 because of logistical supply problems. In several meetings and discussions with USMC and U.S. Navy personnel, this RAM data for using JP-5 in the AVDS-1790 engine which powers the main battle tank (M-48/M-60 Series) was considered to be essential to the USMC. Therefore, prior to adoption of JP-5 as an alternate diesel fuel, the USMC have

* Superscript numbers in parentheses indicate references cited at the end of the report.

requested that a full-scale AVDS-1790-2C engine durability test using the 400-hour mission profile cycle be conducted with JP-5 fuel.

In conjunction with this test, the U.S. Army decided to conduct a parallel program using the research single-cylinder version of the AVDS-1790 engine. This test, performed in cooperation with the USMC request⁽⁶⁾ would provide a means for correlating performance of the single-cylinder CUE version with the full-scale AVDS-1790-2C engine test.

The use of JP-5 in diesel engines has raised the questions of adequate fuel injector lubrication, adequate cetane number, reduced power output, increased fuel consumption, increased engine deposits, and increased engine wear. This test is designed to answer some of these questions.

II. PROCEDURE

A. Performance Test

The engine used in this test was a single-cylinder assembly from the Tele-dyne Continental Motors AVDS 1790-2C 12-cylinder, 4-cycle, diesel engine. The cylinder assembly was mounted on a universal crankcase and designated the CUE (Cooperative Universal Engine) 1790. A photograph of the CUE 1790 is given in Figure 1. Test conditions such as intake air temperature and pressure, exhaust pressure and cylinder cooling air flow were controlled to duplicate the conditions of the full-size AVDS 1790-2C engine. The test instrumentation was calibrated and, as specified by the contract, the performance data were obtained from 1000 to 2400 rpm at the conditions described in Table A-1 of Appendix A. The test fuel was referee-grade DF-2 diesel fuel (AL-7225-F) MIL-F-46162A(MR) Grade II⁽⁷⁾, and the test lubricant conformed to MIL-L-2104C specifications.⁽⁸⁾

B. Endurance Test

The CUE 1790 engine was also used for the 250-hour endurance test. In order to have a base for comparison, the lubricant and test conditions were

FIGURE 1. AVDS 1790-2C SINGLE-CYLINDER ASSEMBLY MOUNTED
ON "COOPERATIVE UNIVERSAL ENGINE" CRANKCASE

made identical to those of a previous 250-hour endurance test in the CUE 1790 using DF-2 (AL-7225-F) as the fuel.⁽⁹⁾ These test conditions are described in Table B-1 of Appendix B. Using the DF-2 endurance test as the basis for comparison would allow determination of differences between test results with DF-2 and JP-5.

For the endurance test, a new cylinder assembly was measured and installed. The engine was run for 20 hours per day at test conditions and was shut down for the remaining 4 hours per day. At the test times listed in Table B-11 of Appendix B, oil samples were taken for laboratory analysis of the lubricant, and oil additions were recorded. At the end of the 250-hour test, the cylinder assembly was disassembled, the critical engine dimensions were remeasured, and the components were rated for deposits according to Coordinating Research Council (CRC) methods for diesel engines. The test fuel and test lubricant for the endurance test were identical to the ones used in the performance test.

III. RESULTS AND DISCUSSION

Table 1 summarizes the performance and endurance tests performed during this program. The table compares power, fuel consumption, wear, deposits, engine component condition, and oil consumption when using DF-2 versus using JP-5 fuels. A more detailed discussion is included in the following sections.

TABLE 1. SUMMARY OF THE EFFECTS OF JP-5 VERSUS DF-2
IN THE SINGLE CYLINDER CUE 1790 DIESEL ENGINE

| Performance (1000-2400 rpm; rated power) | DF-2 | JP-5 |
|--|-----------------|-----------------|
| Average Power, Bhp (kW) | 43(32) | 43(32) |
| Average BSVC, gal./Bhp-hr (l/kW-hr) | 0.062(0.315) | 0.064(0.325) |
| Endurance (250-hr steady-state test) | | |
| Average Cylinder Liner I.D. Change, in. (mm) | +0.0005(+0.013) | +0.0004(+0.010) |
| Average Piston Skirt O.D. Change, in. (mm) | -0.0009(-0.023) | -0.0015(-0.038) |

| Engine Deposits and Condition | | |
| Description of Rings, Pistons, Valves, Cylinder Rod Bearing, and Fuel Injector | Normal | Normal |

* Weighted Total Deposit

A. Performance Test

Table A-2 of Appendix A gives the results of the performance test. The differences in power when changing from DF-2 to JP-5, across the engine speed range tested, ranged from a 4-percent loss to a 3-percent increase. The average change in power was 0 percent. The differences in fuel consumption when changing from DF-2 to JP-5 in the CUE 1790 range from no change to a 5-percent increase in fuel consumption, with the average being a 3-percent increase.

Since diesel engine injection systems supply fuel on a volumetric basis, the conventional measure of fuel consumption, brake specific fuel consumption (BSFC), having units of lb/bhp-hr or kg/kW-hr did not correctly show the differences in fuel consumption and vehicle range between fuels that had much different densities. As a result of this, a different measure of fuel consumption was adopted, having the name brake specific volumetric consumption (BSVC) and the units of gal./bhp-hr or l/kW-hr.

Figures A-1 to A-3 (Appendix A) are included to show the general changes in torque, power, and BSVC with rpm. Note that the DF-2 and JP-5 data points on the torque and power curves are quite close to each other in most cases, and that the torque or power points of neither fuel are distinctly above or below the other across the rpm range. This is in agreement with the average change in power of 0 percent mentioned earlier. In the BSVC curve, the JP-5 points are consistently above the DF-2 points, indicating an increase in fuel consumption. This increase agrees with the 3-percent average increase in fuel consumption calculated in Table A-2.

The percentage figures given for changes in power and fuel consumption have a tolerance of approximately ± 1 percent. When utilizing these percentage figures, the tolerance should be included for effective interpretation.

B. Endurance Test

Tables B-2 and B-3 of Appendix B summarize the operating conditions for the DF-2 and JP-5 endurance tests, respectively. These summaries are a measure

of the constancy of test conditions achieved for the tests. The mean is the average value for the variable, and the standard deviation is a measure of how closely the variable was controlled around the mean.

Tables B-4 and B-5 of Appendix B present the before and after test measurements of critical engine components for the DF-2 and JP-5 tests, respectively.

Comparison of the two tables shows that cylinder liner wear between the two fuels is identical within the measuring limits. The measurements that show a decrease in inside diameter are not considered to be the result of wear and are not included in the consideration of relative wear. The piston skirt diameter changes are within 0.0006 inch (0.015 mm) of each other and can be taken to be identical. The piston ring end gaps showed an average 0.002 inch (0.05 mm) increase in the DF-2 test and an average 0.000 (0.00 mm) inch change in the JP-5 test. Therefore, ring wear appears to be slightly less with JP-5 as a fuel.

Tables B-6 and B-7 of Appendix B show the CRC deposit ratings of the CUE 1790 rating piston for each test. Being a numerical rating, it is a precise way to indicate the quantity and type of deposits. Examination of the ratings indicates that the DF-2 piston had 100-percent hard carbon in the Nos. 1 and 2 ring grooves, while the JP-5 piston had only 45- and 65-percent hard carbon in the Nos. 1 and 2 ring grooves, respectively. The ring lands of the JP-5 piston also had a lower carbon demerit rating than the DF-2 piston. The lacquer ratings indicate that there was no appreciable lacquer on the DF-2 piston, while there was some light lacquer on the JP-5 piston. A 22-percent lower weighted total piston deposits rating illustrates that the piston in the JP-5 fueled engine had significantly less deposits than the DF-2 fueled engine.

The two tables (Tables B-8 and B-9) that describe the deposits and condition of engine components show that the components of both test engines are virtually identical. The exception is the lower carbon deposit demerit ratings that were given to the JP-5 fueled engine parts, which is in accordance with the previously discussed piston ratings.

Examination of the fuel injector revealed that the JP-5 injector resembled the condition of the DF-2 fueled injector quite closely. The only observable difference was that the JP-5 injector had a small (1 mm x 6 mm) gall on the upper portion of the pintle. The DF-2 injector had very slight galls on the pintle upper portion. Neither pintle had step wear on the tip or enlarged nozzle holes. Both had very clean pintles with varnishing of the tip. In view of the limited data, the similarity of the general condition of both injector nozzles, and other reports⁽³⁾, the small gall on the JP-5 injector is not considered fuel-related wear.

Table B-10 of Appendix B presents the total oil consumption for both tests and Figure B-1 of Appendix B presents the same data graphically. From the table and graph, it can be seen that the total oil consumption for the tests are quite close to each other, giving identical rates of consumption. The knee in the DF-2 oil consumption graph can be attributed to the nonregular addition of oil during that portion of the test. Table B-11 of Appendix B gives the characteristics of the new oil and the change in oil characteristics with time during the JP-5 test. Figures B-2 through B-5 give the infrared spectra of the oil as the test progresses. Nothing unusual or excessive was noted in the oil analyses. Since the CUE 1790 engine has a large crankcase oil volume relative to the power of the engine, the oil remains relatively unstressed and stable for the test period. If the fuel causes the oil to degrade, leading to excess deposits, then the large sump volume may understate the effects of the fuel on the engine.

As indicated by the operating conditions summary, the power remained constant throughout the test. There was no drop in power as the test progressed to indicate increasing wear in the injection nozzle, rings, valves, or other components.

IV. CONCLUSIONS

Using JP-5 in the CUE 1790 engine resulted in a slight increase in fuel consumption, although power was unaffected. It also resulted in no change to slightly less wear, less deposits, and no change in the oil consumption. Analysis of the JP-5 indicated that with a cetane number of 51, it meets the

minimum VV-F-800B diesel fuel minimum cetane number specification of 45 (see Table 2). From these facts, the conclusion can be drawn that JP-5, using a MIL-L-2104C lubricant, is considered to be a satisfactory alternative fuel in the AVDS 1790-2C diesel engine.

Since this is a single test of the compatibility of JP-5 in the CUE 1790 engine, the effect of random variables on the test results can not be evaluated.

Statistical analysis of a number of identical tests would provide a measure of the variance of test results and greatly increase the confidence that can be placed in the test results.

V. RECOMMENDATIONS

To provide greater insight as to potential performance limitations arising from the use of JP-5 in other ground-based equipment, the following actions are recommended:

- Conduct a series of identical engine tests of JP-5 in the CUE 1790 engine, or another single cylinder version of the AVDS 1790 more suited to lubricant testing than the CUE 1790, in order to increase the data base and thus the accuracy of the test results.
- Conduct a series of identical full-scale engine tests of JP-5 in the AVDS 1790-2C engine. Testing in the full-scale engine would yield results more representative of field testing than the CUE 1790 engine tests, although far more costly, and the series of tests would increase the accuracy of the test results.
- Conduct series of identical full-scale engine tests of JP-5 in the other engines of the Army inventory. The information gained by testing JP-5 in one type of engine cannot necessarily be extended to other types of engines.

TEST OIL: MIL-L-2104C (AL-6856-L)

DATE COMPLETED: 15 June 1978

RINGS: All rings are free in their grooves.
No ring face burning.
Normal wear pattern.
All oil control ring slots open.
No. 2 compression ring ID has some heavy carbon.

PISTON: Light scratches (see piston rating sheet).

VALVES: There is some carbon on the intake valve face and corresponding pits in the valve seat.
Intake valve tulip deposit rating: 1.0
Exhaust valve tulip deposit rating: 0.25

CYLINDER: Light lacquer on liner.
Normal light scratches.

CONNECTING ROD BEARING: Normal light wear on the top half.

FUEL INJECTOR: Light, normal wear on pintle. No step wear on pintle tip. Nozzle holes not enlarged. Pintle clean and has some very light galling on the upper portion.

TABLE B-9. ENGINE COMPONENTS
DEPOSITS AND CONDITION DESCRIPTIONS

ENGINE: CUE 1790

TEST FUEL: JP-5 (AL-8570-F)

TEST OIL: MIL-L-2104C (AL-6856-L)

DATE COMPLETED: 30 August 1979

RINGS: All rings are free in their grooves
No ring face burning.
Normal wear pattern.
All oil control ring slots open.
No. 2 compression ring ID has some heavy carbon.

PISTON: Light scratches (see piston rating sheet).

VALVES: The intake valve has some pitting on the valve face and has
a No. 5 lacquer deposit rating.
Intake valve tulip deposit rating: 0.5
Exhaust valve face is normal and has a No. 9 lacquer deposit
rating.
Exhaust valve tulip deposit rating: 0.25

CYLINDER: Light carbon in combustion chamber.
Light lacquer on liner.
Very light wear.

CONNECTING ROD BEARING: Normal light wear on the top half.

FUEL INJECTOR: Light, normal wear on pintle. A slight galling
(1mm x 6 mm) was noted on the upper portion of the
pintle. The pintle tip had no step wear and the
nozzle holes were not enlarged from their original
dimension. Pintle very clean, no varnish or deposits
on body. Pintle tip has some varnish.

TABLE B-10. DF-2 AND JP-5
ENDURANCE TESTS
OIL CONSUMPTION

| DF-2 | | JP-5 | |
|------------------|---------------------------------|------------------|---------------------------------|
| Test Time, hr | Total Consumption, lb(kg) | Test Time, hr | Total Consumption, lb(kg) |
| 0 | 0(0) | 0 | 0(0) |
| 9 | 0(0) | 20 | 7.14(3.24) |
| 15 | 7.58(3.44) | 56 | 9.22(4.19) |
| 26 | 7.58(3.44) | 84 | 15.49(7.03) |
| 39 | 7.58(3.44) | 98 | 17.61(7.99) |
| 55 | 14.17(6.43) | 126 | 24.21(10.99) |
| 69 | 27.77(12.61) | 168 | 30.03(13.63) |
| 84 | 28.27(12.83) | 200 | 36.41(16.53) |
| 99 | 28.27(12.83) | 210 | 39.39(17.88) |
| 114 | 28.27(12.83) | 224 | 43.09(19.56) |
| 129 | 28.39(12.89) | 238 | 50.11(22.75) |
| 144 | 30.29(13.75) | | |
